Preface

This guide is provided as-is and was compiled by a bunch of students in 2016. We tried our best to be mathematically and technically accurate. But software versions (Ver 2.04 now) do change, and this guide may not be valid indefinitely. However, the source of this file is publically available on GitHub. Feel free to contact us.

If there are anything you want to do, but you can't seem to know how to, try Google, or RTFM. Otherwise, just experiment a bit. The CASIO interface should be intuitive enough.

Do note that some notes inside this guide was taken from the H2 Mathematics notes provided by the Hwa Chong Institution (College Section) Math Department.

Chapter 1

The Basics

Every command you will ever need is organized neatly in the [OPTN] button on your graphing calculator (GC).

Unfortunately there are some areas where the CASIO calculator isn't very intuitive and we need some documentation.

1.1 Graphing

To graph a function, go to **GRAPH** in the main menu. Enter the functions into **Y1** onwards. Press **[EXE]** to graph. Most of these are pretty intuitive, just some things you should take note:

- The **Y** and **X**, etc. at the bottom of the screen is for entering the functions **Y1**, **Y2**, ... and **X1**, **X2**, For the variable x , use the **[X,θ,T]** button instead

- To restrict the domain of the function, type:

$$Y1 = f(x), [\text{start}, \text{end}]$$

After pressing **DRAW**, you can press **[AC/on]** to break the plotting script.

To solve for anything, use **[G-Solv]**.

1.1.1 Plotting a table from function

Plot using function

1.2 Solving for the roots of a polynomial

There are mainly 2 ways to solve for the roots of a polynomial using the GC:

- Using the **EQUA > Poly** app
- Plot a graph and solve for roots

The **EQUA > Poly** is quite intuitive, and similar to the standard issue **CASIO fx-95SG** scientific calculator, so we will just note some limitation/features of this GC:

- The polynomial solver only accepts real coefficients
- You can change the **Set Up > Complex Mode** setting to $a + bi$ for imaginary roots (but not imaginary coefficients)

To plot a graph, you go to **Graph**. Refer to Section 1.1 (Graphing) for more information.

1.3 Solving a 1-variable Equation

There are mainly 2 ways to solve a 1-variable equation (e.g. $e^x + 5x = 1$) using the GC:

- Using the **EQUA > Solver** app
- Plotting a graph
 - Move everything to one side and solve for root
 - Solve for the intersections of 2 or more graphs

1.3.1 Solving using EQUA > Solver

note that typing X in run mat will give back ans

1.4 Taking Integrals

introduce the Math functions in the main RUNMAT

Chapter 2

Vectors

Chapter 3

Statistics

One major use of a graphing calculator is for use in statistics. In the following chapters, we will outline the methods with which we can use our GC. Calculator functions in this section can generally be found under [OPTN] > [STAT]. Permutation and Combinations will not be covered. Calculated variables can be found under [VARS] > [STAT]

3.1 Discrete Random Variable

A discrete (countable) random variable $X \in \mathbb{Z}^*$ has expectation (or expected value or mean) μ

$$E(X) = \mu = \sum_{\text{all } x} xP(X = x) \quad (3.1)$$

(You can think of this as the weighted sum of all the possibilities for X)

and variance $\sigma^2 = \text{stddev}^2$

$$\text{Var}(X) = \sigma^2 = E(X - \mu)^2 = E(X^2) - \mu^2 \quad (3.2)$$

Note: The above does not apply to continuous random variables.

3.1.1 Using Data

If given a set of histogram data (i.e. categories and its corresponding frequencies), one can calculate statistical properties of it.

For example, given the following data:

x	0	1	2	3
$P(X = x)$	$\frac{1}{8}$	$\frac{3}{8}$	$\frac{3}{8}$	$\frac{1}{8}$

You can do 1-Variable Statistical calculations by:

1. Go into **STAT** and then enter the X-values into **List 1** and its frequency into **List 2**
2. go to **CALC > SET** and adjust the settings accordingly for 1-Var (**XList:List1, Freq:List2**)
3. **[EXIT]** and then choose **1VAR**

If you want to further manipulate these calculated values (such as squaring σ to find variance), you can go to `RUN·MAT` and then `[VARS] > [STAT] > [X]` to finding the value(s) you wanted.

Refer to Section 3.3.1 (Plotting Statistics/Visualization) for plotting statistical data.

3.1.2 Binomial Distribution

A binomial random variable X has the following characteristics:

1. The experiment consists of n repeated independent trials
2. Each trial only has 2 outcomes: "success" or "failure"
3. The probability of a 'success' p is constant in each trial

The probability $P(X = x)$ of obtaining x successes in n trials is given by:

$$P(X = x) = \binom{n}{x} p^x (1 - p)^{n-x}, \quad x \in \mathbb{Z}^* \quad (3.3)$$

and has $E(X) = np$ and $\text{Var}(X) = np(1 - p)$.

We write $X \sim B(n, p)$.

Note: the probability is only non-zero when $0 \leq x \leq n$ (i.e. there is an upper bound).

To obtain the probability $P(X = x)$, we can either use the formula, or use the in-built `BinomialPD` function:

`BinomialPD(X,n,p)`

To obtain the probability $P(X \leq x)$ (*cumulative distribution function* of x), we can use the in-built `BinomialCD` function:

`BinomialCD(X,n,p)`

As a general rule of thumb:

Answer in:	Use:
\mathbb{Z}	Table
\mathbb{R}	Graph

Refer to Section 1.1.1 for plotting results from a table, which might be useful for plotting the PDF/CDF of a binomial distribution, since $P(X = x)$ is undefined when $x \notin \mathbb{Z}^*$

3.2 Continuous Random Variable

The probability for a continuous variable X to fall within a particular region $[a, b]$ is given by:

$$P(a \leq X \leq b) = \int_a^b f(x)$$

where $f(x)$ is the *probability density function* (PDF) of X .

Moreover,

$$P(a \leq X \leq b) = P(a \leq X < b) = P(a < X \leq b) = P(a < X < b)$$

3.2.1 Normal Distribution

A (continuous) random variable $X \in \mathbb{R}$ that follows a normal distribution with mean μ and standard deviation σ has a *probability density function* (PDF) given by:

$$f(x) = \frac{1}{\sigma\sqrt{2\pi}} \cdot e^{-\frac{(x-\mu)^2}{2\sigma^2}} \quad (3.4)$$

We write $X \sim N(\mu, \sigma^2)$

Normal Distribution PDF

There are one of 2 ways to plot a graph of the normal distribution PDF:

- Plot the actual equation
- Use the in-built `NormPD` function

However, it must be noted that the `NormPD` plots slower than using the actual equation. Using `G-Solv` is also slower.

The usage of `NormPD` is

$$\text{NormPD}(X, \sigma, \mu)$$

This is the same command you type if you want to calculate the probability of a certain random variable $P(X = x)$ where $x \in \mathbb{R}$.

Normal Distribution CDF

CDF stands for *Cumulative Distribution Function*. This can be calculated by taking the integral of the normal PDF from 0 to x . One can take integral by plotting the graph out (refer to previous section), and then $\text{G-Solv} > \int dx$.

Alternatively, you can use the built-in `NormCD`:

$$\text{NormCD}([\text{Lower}], [\text{Upper}], \sigma, \mu)$$

To plot the Normal Distribution CDF, you can use:

$$Y = \text{NormCD}(-1\text{E}99, X, \sigma, \mu)$$

Note: $-1\text{E}99$ is to simulate $-\infty$.

Finding the value given the probability

One sometimes need to find a given $P(X < a) = b$ where $a, b \in \mathbb{R}$ and b is the probability of X being less than a .

To do this, we need the `InvNormCD` function built into the calculator. The usage of `InvNormCD` is as follows:

$$\text{InvNormCD}(b, \sigma, \mu)$$

This will give you back a .

3.3 Use for Experimental Data/SPA

lin regression -i ref to lin alg best approximations

3.3. *USE FOR EXPERIMENTAL DATA/SPA*

Chapter 4

Linear Algebra

Some of you might find yourself doing linear algebra, and needing to do matrix manipulations. In this chapter, I will outline some basic concepts covered in MA1101R (NUS H3 Course), and how you can use your GC to find the answer.

You may find certain concepts here useful for H2 Mathematics as well, especially in terms of matrix manipulations. I suggest you read this chapter as a complement of Chapter 2 (Vectors).

4.1 Storing Matrices

accessing individual matrix elements

4.2 Solving Linear Systems

introduce augmented matrix how to augment if 2

4.2.1 Elementary Row Operations and Row-Echelon Forms

row equiv
